## TITLE OF INVENTION

Analyser arrangement.

## FIELD OF INVENTION

5 The present invention relates to analyser arrangements.

More particularly, the present invention relates to analyser arrangements for online spectral analysis of mineral streams.

## BACKGROUND TO INVENTION

10 In order to control mineral processing plants, determination of mineralogical composition of various streams in the plant is required. Known methods include grain-counting techniques. However, in some cases data automation of this process does not produce reliable results and only manual methods prove to be reliable. Furthermore, the determination of elemental chemical composition alone (XRF - X-ray  
15 fluorescence spectrography) does not provide all the necessary information. Furthermore, due to the variability in chemical composition it is not possible to utilise this method for the exact description of mineralogical composition. Accordingly, automation of the mineral analysis procedure is required.

20 It is an object of the invention to disclose an analyser arrangement for online spectral analysis of mineral streams.

## SUMMARY OF INVENTION

According to the invention, an analyser arrangement for determining the composition of a mineral stream, includes online spectral analysis means for determining the composition of a mineral stream.

5 Also, according to the invention, a method of determining the composition of a mineral stream, includes the steps of

- (a) illuminating a mineral stream to cause light reflection therefrom;
- (b) sensing the light reflected by the mineral stream; and
- 10 (c) analysing the light reflected by the mineral stream by spectral analysis to determine the composition of the mineral stream.

The online spectral analysis means may include

- (a) illumination means for illuminating the mineral stream to cause light reflection therefrom;
- 15 (b) sensing means for sensing the light reflected by the mineral stream;
- (c) a spectrometer for analysing information supplied by the sensing means, and thereby determining the spectral distribution of the reflected light; and
- 20 (d) a data processor for evaluating information supplied by the spectrometer and thereby determining the composition of the mineral stream.

The illumination means and sensing means may be associated with a probe.

A mechanical shield may be provided to shield the probe from the mineral stream.

- 5 The mechanical shield may include scraping means for scraping the surface of the mineral stream for facilitating internal illumination and sensing of the mineral stream.

A light shield may be provided to limit external light from influencing the sensing of the sensing means.

- 10 The probe may include optical fibres.

The illumination means may include illuminating fibres.

The sensing means may include sensing fibres.

The illumination means may emit UV (ultra-violet), and/or visible and/or IR (infra-red) light.

- 15 The processor may identify the spectral identities of minerals in the mineral stream.

The processor may calculate the quantity of each mineral in the mineral stream.

- 20 The analyser arrangement may provide real-time information of the mineral composition.

The analyser arrangement may be provided with operation means for automatic control of a mineral processing plant.

The analyser arrangement may be calibrated by means of a bench-top mineral analyser.

The analyser arrangement may be provided with an additional light source.

## 5 BRIEF DESCRIPTION OF DRAWINGS

The invention will now be described by way of example with reference to the accompanying schematic drawings.

In the drawings there is shown in:

- Figure 1: a perspective view of an analyser arrangement in accordance  
10 with the invention;
- Figure 2: a front view of the analyser arrangement seen along arrow II  
in Figure 1;
- Figure 3: a top view of the analyser arrangement seen along arrow III  
in Figure 1; and
- 15 Figure 4: a sectional side view of the analyser arrangement seen along  
arrows IV-IV in Figure 3.

## DETAILED DESCRIPTION OF DRAWINGS

Referring to Figures 1 to 4, an analyser arrangement for online analysis of a mineral stream in order to determine the composition of the mineral  
20 stream, generally indicated by reference numeral 10, is shown.

The analyser arrangement 10, in use located in proximity of mineral conveying means 12, such as a conveying belt, and conveying a mineral

stream 14 to be analysed, includes a probe 16 positioned close to the moving mineral stream 14. The mineral stream 14 in the embodiment example consists of dry minerals.

5 The probe 16 is provided with two types of optical fibres (not shown), illuminating fibres and sensing fibres. Light emitted by the illuminating fibres is selectively reflected by the minerals in the mineral stream 14, and the reflected light is picked up by the sensing fibres, whereafter information is sent via the probe output 18 to a spectrometer (not shown) which senses the spectral distribution of the light reflected by the minerals  
10 in the mineral stream 14, and transmits the output to a data processor (not shown). The output of the data processor includes seven 4-20 mA signals, each corresponding to a percentage of mineral occurrence.

The light emitted by the illuminating fibres include visible and NIR (near infra-red) reflected according to the mineral composition and impurities  
15 therein. Accordingly, the spectrometer is classified as a visible and NIR spectrometer.

The processor thereafter identifies the digital output or spectral "fingerprints" of the different minerals in the mineral stream 14, and calculates the abundance of each mineral of concern in the mineral  
20 mineral 14. The processor output may include an operator user-friendly interface.

Furthermore, the analyser arrangement 10 is provided with an additional light source 20 for illuminating the mineral stream 14.

Also, the analyser arrangement 10 is provided with a mechanical shield 22  
25 to shield the probe 16 from the mineral stream 14, i.e. for scraping the

surface of the mineral stream 14 to enable the probe 16 to internally illuminate the mineral stream 14.

Calibration of the analyser arrangement may be achieved by means of a bench-top analyser model where changes in the mineralogy of the mineral stream 14 occurs.

The implementation of the analyser arrangement is achieved in various phases, namely:

- (a) Amenability study;
- (b) Desktop analyser arrangement; and
- (c) ON-line analyser arrangement.

During the amenability study phase, a representative set of mineral samples is obtained by the user. The number of known samples required at this stage is  $n=(m+1)^2$ , where  $n$  is the number of samples, and  $m$  is the number of mineral mixtures to be differentiated. The accuracy of the composition of these samples determines the final accuracy of the analyser arrangement according to the invention. An analysis and training set for the specific set of minerals is performed, and an expected level of accuracy is calculated.

During the desktop analyser arrangement phase, a desktop analyser, set up according to the results of the amenability study, is constructed and includes:

- An industrial computer preloaded with analysis and data storage software,

- A spectrometer,
- A light source, and
- A probe assembly.

Initially, the system is provided with rough calibration and tuning,  
5 however final tuning has to be performed over a time span, for example  
four to eight weeks, in order to achieve full accuracy.

The spectral data of several samples and the known values for these  
samples are determined and thereafter utilised for obtaining final tuning  
parameters, to be loaded in the bench top model.

- 10 Finally, during the on-line analyser arrangement phase, the on-line  
analyser arrangement in accordance with the invention is constructed.

Accordingly, the analyser arrangement 10 in accordance with the invention provides an arrangement and method to achieve accurate and frequent measurements of mineral streams in mineral processing operations. The on-line analyser arrangement provides mineral  
5 concentrator operations with real-time information of the mineral composition of mineral streams and provides the option of automatic control.
